## Product Information Report End Mills

## Overview

An end mill is a cutting tool used in industrial machining applications. An end mill bit can generally cut in all directions, though some cannot cut axially. End mills are used in milling applications such as profile milling, tracer milling, face milling and plunging.

## What are the Different Types of End Mills?

A broad category of end mills exists, such as single end, double end, center-cutting, non center-cutting, ball nose and roughing.
Each category may be further divided by application and special geometry. End mills are sold in both imperial and metric sizes, depending on the country of origin.

## Applications

End mills are used in machining applications such as profile milling and face milling. Depending on the material being machined, different tool types and geometries may be used.

## Remember

- Always wear eye protection when using any cutting tool

- Store end mills properly when not in use
$\square$

## What are End Mills <br> Made From?

Lawson carries end mills made from two different materials: M42 cobalt and carbide. Cobalt end mills are ideal for any milling application. Carbide end mills offer higher speed and feed rates, but should only be used on stable, high-end CNC machines.

## M42 Cobalt

2-Flute Single End Center-Cutting
4-Flute Single End Center-Cutting
4-Flute Single End Ball Nose
4-Flute Single End Coarse Rougher
2-Flute Double End Center-Cutting Supertanium ${ }^{\circledR}$ || Triple-Cut (3-Flute) Center-Cutting

## Carbide

2-Flute Single End Center-Cutting
4-Flute Single End Center-Cutting
4-Flute Single End Ball Nose
2-Flute Single End Aluminum Cutting

## Coatings

- TiN - Titanium Nitride (a yellowish coating)

The ideal coating for a wide range of applications, materials and cutting conditions where tool life and higher feeds and speeds are operating objectives. The high lubricity of TiN facilitates chip flow, prevents buildup and reduces cutting forces and temperatures. TiN reduces wear and improves chip formation to extend tool life. It is a good choice for machining iron-based materials, die molds, and for components requiring resistance to abrasive and adhesive wear. This coating is available on Lawson's 2- and 4-flute M42 Cobalt End Mills.

## - TiCN - Titanium Carbonitride (a bluish-grey coating)

This is a coating with exceptionally high hardness and low coefficient of friction which provides excellent wear resistance. TiCN performs well when cutting alloy steels, stainless steels, and in high-speed cutting where moderate temperatures are generated at the cutting edge. TiCN coating provides an excellent surface quality on machined components. It is also excellent for applications which require high feed and speed rates. This coating is available on Lawson's 2-Flute Carbide End Mills for aluminum cutting.

- Nitride/Gold Oxide (a black and gold coating)

Combines the advantages of the lubricity of oxide with the abrasion resistance of nitriding. Recommended for abrasive ferrous applications. Not recommended for soft materials such as aluminum, magnesium or similar non-ferrous applications. This coating is available on Lawson’s Supertanium ${ }^{\circledR} \|$ Triple-Cut (3-Flute) Center-Cutting End Mills.

Utilize the shortest available tool possible for the application with the largest diameter permissible and the shortest flute length that depth of cut allows. The point style of the end mill is also important in determining what end mill should be used.

## End Mill Selection

## Flutes

3-Flute End Mills are more rigid and have less cut interruption than 2-flute designs. They have a higher chip volume area than 4-flute designs for higher metal removal rates. 3-flute end mills have all the machining capabilities of 2 -flute end mills, and are ideal for slotting applications. Improved part finish and dimensional accuracy can be achieved in a wider range of materials than with 2-flute types.

4-Flute End Mills are stronger than either 2- or 3-flute designs. The added rigidity allows higher metal removal rates with minimum deflection. Improved workpiece finishes and dimensional accuracy can be achieved. Limited chip volume area restricts stock removal rates and deep plunge cutting is not recommended. The 4-flute design is commonly used for finishing operations for the best surface finish.

## End Mill Selection (cont.)

## Point Styles

4-Flute

When choosing an end mill, the point style is just as important as the number of flutes or the tool length. Lawson offers 2-, 3- and 4-Flute Center-Cutting, 4-Flute Non Center-Cutting and 4-Flute Ball Nose end mill styles.

## Center-Cutting

At least one of the end teeth extends to the center of the end mill. This allows the end mill to plunge directly into the material because material is removed from the entire diameter.

## Non Center-Cutting

None of the end teeth extend to the center of the end mill. There is a female center on the tip of the end mill where no material would be removed if it was used in plunge milling applications. These end mills are designed primarily for peripheral milling.

## Ball Nose

Ball nose end mills have a rounded point for radiused cutting applications. They are commonly used to machine the rounded grooves for o-rings. Ball nose end mills can be used to plunge cut, but the cut must be combined with the action of a slotting cut. It can not be plunged straight down into the material.

## Types of Milling

## Conventional Milling

Tool Rotation

Climb Milling

Material Direction

## Peripheral Milling

## Plunge Milling/Slotting

(4 of 8)

The end mill revolves opposite to the direction of the table feed. The width of the chip starts at zero and increases to a maximum at the end of the cut. This type of milling can lead to accelerated wear.
Note: Make sure workpiece is secure before beginning milling operation.

The end mill revolves in the same direction as the table feed. The tooth meets the workpiece at the top of the cut, producing the thickest part of the chip first.
Note: Make sure workpiece is secure before beginning milling operation.

The surface is milled parallel to the end mill axis. Peripheral milling can be either conventional or climb milling.

Plunge Milling: The direct movement between the workpiece and the center line of the end mill when the end mill sinks directly into the workpiece. The action of drilling a hole with a centercutting end mill.
Slotting: All slotting applications are a combination of conventional milling and climb milling.

Types of Milling and End Mill Selection
Slotting

## Peripheral Milling

## Plunge Milling

| Cutting Conditions | End Mill | 2-Flute | 3-Flute | 4-Flute |

Best Useable $\boldsymbol{X}$ Do Not Use

## Proper Speeds and Feeds

Before the machining operation can be performed, the proper speeds and feeds need to be selected. Using the proper speeds and feeds for the material being machined extends tool life and the appearance of the machined face.
Lawson's Cobalt and Carbide End Mills each have their own speed and feed charts. Roughing End Mills speed and feed chart is listed below.

Since all speed and feed charts give a range for the speed to use, here are some general guidelines to help determine the proper speed to use.

## Use lower speed ranges for:

Hard Materials
Tough Materials
Abrasive Materials
Heavy Cuts
Minimum Tool Wear
Maximum Cutter Life
Reminder: When using a carbide end mill, the cutting fluid must either be continuously flowing over the end mill or no cutting fluid should be used. Intermittent cooling of a carbide tool can cause it to chip.

## Roughing End Mills Speed and Feed Data

All speeds and feeds are suggested starting points. They may be increased or decreased depending on machine condition, depth of cut, finish required, etc.

## List of Symbols

F = Number of Flutes
D = Cutter Diameter
RPM = Revolutions per Minute
SFM = Surface Feet per Minute
IPM = Inches per Minute Feed Rate
IPR = Inches per Revolution Feed Rate

## Machining Formulas

SFM $=0.262 \times D \times R P M$
$R P M=\frac{3.82 \times \text { SFM }}{D}$

$$
\mathrm{IPR}=\frac{\mathrm{IPM}}{\mathrm{RPM}} \text { or Chip Load } \times F
$$

$I P M=R P M \times I P R$
Chip Load $=\frac{\mathrm{IPM}}{\mathrm{RPM} \times \mathrm{F}}$ or $\frac{\mathrm{IPR}}{\mathrm{F}}$

[^0]| Milling Problems | Possible Cause | Possible Solution |
| :---: | :---: | :---: |
| Chip Packing | Cutting too much material | Adjust feed or speed |
|  | Not enough chip room | Use end mill with fewer flutes |
|  | Not enough coolant | Apply more coolant, use air pressure |
| Rough Surface Finish | Feed too fast | Slow down to correct feed |
|  | Slow speed | Use higher speed |
|  | Too much wear | Regrind earlier stage |
|  | Chip biting | Cut less amount per pass |
|  | No tooth end concavity | Add margin (touch primary with oilstone) |
| Burr | Too much wear on primary relief | Regrind sooner |
|  | Incorrect condition | Correct milling condition |
|  | Improper cutting angle | Change to correct cutting angle |
| No Dimensional Accuracy | Condition too tough | Change to easier condition |
|  | Lack of accuracy (machine and holder) | Repair machine or holder |
|  | Not enough rigidity (machine and holder) | Change machine or holder condition |
|  | Not sufficient number of flutes | Use end mill with greater number of flutes |
| $\begin{aligned} & \text { No } \\ & \text { Perpendicular } \\ & \text { Side } \end{aligned}$ | Feed too fast | Slow down to correct feed |
|  | Too great a cutting amount | Reduce cutting amount |
|  | Too long a flute or overall length | Use proper tool length, hold shank deeper |
|  | Insufficient number of flutes | Use end mill with greater number of flutes |
| Chipping | Feed too fast | Slow down to proper feed |
|  | Feed too fast on first cut | Slow down on first bite |
|  | Not enough rigidity of tool and holder | Change rigid machine tool or holder |
|  | Loose holder | Tighten tool holder |
|  | Loose holder (workpiece) | Tighten workpiece fixture |
|  | Lack of rigidity (tool) | Use shortest end mill available, hold shank deeper, try down cut |
|  | Teeth too sharp | Change to lower cutting angle, primary relief |
| Wear | Speed too fast | Slow down, use more coolant |
|  | Hard material | Use higher grade tool material, add surface treatment |
|  | Biting chips | Change feed speed to change chip size or clear chips with coolant or air pressure |
|  | Improper feed speed (too slow) | Increase feed speed, try down cut |
|  | Improper cutting angle | Change to correct cutting angle |
|  | Primary relief angle too low | Change to larger relief angle |
| Breakage | Feed too fast | Slow down feed |
|  | Cutting amount too large | Adjust to smaller cutting amounts per tooth |
|  | Flute length or overall length too large | Hold shank deeper, use shorter end mill |
|  | Too much wear | Regrind at earlier stage |
| Chattering | Feed and speed too fast | Correct speed and feed |
|  | Not enough rigidity (machine and holder) | Use better machine tool or holder or change condition |
|  | Relief angle too large | Change to smaller relief angle, add margin (tough primary with oil stone) |
|  | Loose holder (workpiece) | Hold workpiece tighter |
|  | Cutting too deep | Correct to smaller cutting depth |
|  | Flute length or overall length too large | Hold shank deeper, use shorter end mill or try down cut |
| Short Tool Life (Dull Teeth) | Cutting friction too high | Regrind at earlier stage |
|  | Tough work material | Select premium tool |
|  | Improper cutting angle | Change cutting angle and primary |

[^0]:    NOTE：All speed and feed data are suggested starting points．They may be increased or decreased depending on machine condition，depth of cut，finish required，coolant，
    etc．When using TiN－coated M42 cobalt cutters，increase speed rate by $25 \%$ ．
